SUPPORT AND SALES

**DATA IMAGING PTY LTD**

**A U S T R A L I A**

*Patents Act 1990*

**PROVISIONAL SPECIFICATION**

for the invention entitled:

**"An imaging process for financial data"**

The invention is described in the following statement:

## **AN IMAGING PROCESS FOR FINANCIAL DATA**

### **FIELD OF THE INVENTION**

The present invention relates to an imaging process, and in particular to a system and  
5 process for generating image display data to represent financial data for a financial  
product, such as a managed or mutual fund, or shares or stocks in a company.

### **BACKGROUND**

Financial data can be difficult to comprehend, particularly for non-experts. Consequently,  
many people rely on investment advisors and other consultants to provide advice in  
10 relation to financial products such as shares or stocks and managed funds or mutual funds.  
Yet consultants can be expensive and introduce a further layer of difficulty for lay persons.

To evaluate different investment options, it is often helpful if complex financial data can  
be graphically represented to enable important characteristics and trends to be determined  
15 by visual inspection. This can be particularly important when two or more financial  
products are to be compared, where each product is characterised by various financial data  
parameters. For example, owners of and investors in financial products such as shares or  
stocks, bonds, mutual and other managed funds, need to make judgements based on the  
past, current and prospective values of these assets in order to make buy, hold, and/or sell  
20 decisions. However, currently available systems and processes for graphically  
representing financial data for such products are overly complex for non-expert users. For  
example, multiple stock or share parameters are typically viewed as text, tables and/or two  
dimensional graphs or charts that are often difficult to comprehend, and presume a high  
level of expert knowledge. Consequently, assessing the quality of selected stocks is  
25 particularly difficult for non-experts, and this affects the quality of an individual's  
investment decisions.

It is desired, therefore, to provide a system and process for generating image display data  
using financial data that alleviate one or more difficulties of the prior art, or at least

- 2 -

provide a useful alternative. In particular it is desired to provide an imaging process and system which allow a lay person to readily assess fundamental characteristics of a financial product without having to possess expertise in financial analysis.

## 5 SUMMARY OF THE INVENTION

In accordance with the present invention, there is provided an imaging process including generating image display data representing a three-dimensional object at the origin of a spatial coordinate system, the dimensions of said object being determined on the basis of financial data for a financial product.

10

Preferably, said object is represented isometrically by said display data.

Preferably, said object is a cuboid or rectangular parallelepiped.

15 Advantageously, the dimensions of said object may correspond to respective parameters of said financial data.

Advantageously, the colour of said object may be determined on the basis of said financial data.

20

Advantageously, the colour of said object may be determined on the basis of a parameter of said financial data.

Advantageously, said parameter may be a measure of risk for said financial product.

25

Preferably, the parameters of said financial data for said financial product are normalised with respect to respective parameters of financial data for the overall market for said financial product.

---

- 3 -

Advantageously, the parameters of said financial data for said financial product may be quantized.

5 Preferably, the process includes generating display data for displaying a financial data value for said financial product in response to movement of a pointing device over a corresponding portion of an image generated from said image display data.

Advantageously, the process may include regenerating said image display data to reflect changes in said financial data.

10

Advantageously, said image display data may include image animation data for generating an animated representation of said object representing changes of said financial data over time.

15 Advantageously, said financial product may be a stock.

Advantageously, said parameters may be selected from price, income, growth, return on assets, debt to equity ratio, and volume of trading or another financial measure of said stock.

20

Advantageously, said dimensions of said object may correspond to respective measures of price, income, and growth of said stock.

25 Preferably, said measures correspond to price to earnings ratio, dividend yield, and growth in earnings per share.

Preferably, said measures are normalised with respect to respective measures for the overall market for said stock.

30 Advantageously, the colour of said object may be determined on the basis of a risk measure for said stock. Preferably said risk measure is the beta value for said stock.

- 4 -

Advantageously, said financial product may include a managed fund or a mutual fund.

Advantageously, said financial product may represent an aggregate of funds and/or stocks.

5

Advantageously, said dimensions may correspond to respective measures selected from financial return, rolling return, entry fee, management expense ratio, and independent rating or another financial measure for said fund.

- 10 Advantageously, said dimensions may correspond to measures of financial return over respective periods of time for said fund.

Advantageously, said periods may be specified by a user.

- 15 Preferably, said periods correspond to 1, 3, and 5 year periods.

Advantageously, the colour of said object may be determined on the basis of a risk measure for said fund. Preferably said risk measure represents the volatility of said fund.

- 20 Preferably, said measures are normalised with respect to funds in the same fund category.

Advantageously, the process may include generating display data representing two or more objects for respective financial products to enable comparison of said financial products, wherein the dimensions of each object are determined on the basis of financial data for the

25

corresponding financial product.

Advantageously, the process may include generating display data representing two or more objects for respective financial products to enable comparison of said financial products, wherein the colour of each object is determined on the basis of financial data for the

30

corresponding financial product.

- 5 -

Advantageously, said image display data may represent said two or more objects at the origin of a spatial coordinate system.

Advantageously, said image display data may represent said two or more objects at the  
5 origins of respective spatial coordinate systems.

Advantageously, said financial product may include a stock or a managed fund or mutual fund.

10 Advantageously, the process may include receiving transaction data in respect of a financial product from a user, and initiating a financial transaction on the basis of said transaction data.

Advantageously, said initiating may include initiating a financial transaction with a remote  
15 transaction system.

Advantageously, the process may include selecting at least one financial product on the basis of a comparison of financial data for said at least one financial product with predetermined financial data.

20

Advantageously, said predetermined financial data may be specified by a user.

Advantageously, the process may include selecting at least one financial product corresponding to a selected financial product category.

25

Advantageously, the process may include selecting at least one financial product on the basis of a comparison of financial data for said at least one financial product with corresponding financial data for another selected financial product.

- 6 -

Advantageously, each said at least one financial product may be selected if the dimensions of an object represented by image display data for said at least one financial product are similar to those of the selected financial product.

- 5 Advantageously, each said at least one financial product may be selected if the colour of an object represented by image display data for said at least one financial product is similar to that of the selected financial product.

Advantageously, the process may include generating a display of said image display data.

10

The present invention also provides an imaging process, including generating image display data representing a three-dimensional object, the dimensions and colour of said object being determined on the basis of financial data for a financial product.

- 15 The present invention also provides an imaging process, including generating image display data representing a three-dimensional object, the respective dimensions of said object being determined on the basis of price, income, and growth of a stock.

Advantageously, the colour of said object may be determined on the basis of a beta value  
20 for said stock.

The present invention also provides an imaging process, including generating image display data representing a three-dimensional object, the dimensions of said object being determined on the basis of performance data for a fund over respective time periods.

25

Advantageously, the colour of said object may be determined on the basis of a measure of volatility for said fund.

Preferably, said periods are periods of one, three, and five years.

30

- 7 -

The present invention also provides a system having components for executing the steps of any one of the above processes.

5 The present invention also provides program code for executing the steps of any one of the above processes.

The present invention also provides a computer readable storage medium having stored thereon program code for executing the steps of any one of the above processes.

10 The present invention also provides a graphical user interface, including a representation of a three-dimensional object at the origin of a spatial coordinate system, wherein the dimensions of said object are determined on the basis of financial data for a financial product.

15 The present invention also provides an imaging system, including a visualisation module for generating image display data representing a three-dimensional object at the origin of a spatial coordinate system, wherein the dimensions of said object are determined on the basis of financial data for a financial product.

20 Advantageously, the system may be adapted to receive said financial data from a remote system to enable said visualisation module to update said image display data.

Preferably, the system includes a server for receiving a request for said image display data and for sending said image display data in response to said request.

25

Preferably, the system includes a transaction module for initiating a financial transaction on the basis of received transaction data in respect of a financial product.

## BRIEF DESCRIPTION OF THE DRAWINGS

Preferred embodiments of the present invention are hereinafter described, by way of example only, with reference to the accompanying drawings, wherein:

Figure 1 is a block diagram of a preferred embodiment of an imaging system  
5 connected to remote computer systems via a communications network;

Figure 2 is a flow diagram of an imaging process executed by the imaging system;

Figure 3 is a flow diagram of a financial product selection process executed by the imaging system; and

Figures 4 to 17 are screenshots generated by the imaging system.  
10

## DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

An imaging system, as shown in Figure 1, is used to generate images for visualising financial data associated with one or more financial products, such as shares, also known as stocks, and managed funds, also known as mutual funds. The imaging system includes a  
15 network interface 100 and imaging modules 102 to 112, comprising a web server 102, visualisation scripts 104, a transaction engine 106, a scripting language module 108, a database interface module 110, and a database 112. The imaging system provides an evaluation tool and can be accessed as part of, or even integrally provides, a network site for a broker or broking institution, such as Goldman Sachs (<http://www.gs.com>) or Charles Schwab (<http://www.schwab.com>). The imaging system can be connected to remote  
20 systems, such as a client system 114 and a stock exchange system 116, via the network interface 100 and a communications network 118, such as the Internet. In the described embodiment, the imaging system is a standard computer system, such as an Intel™-based high-performance server executing a Linux™ operating system and the network interface  
25 100 is a standard network interface connector such as a 3Com Etherlink 3 Vortex Ethernet card. The web server module 102 is a standard web server, such as Apache, available at <http://www.apache.org>, the scripting language module 108 is a standard scripting language module such as PHP, available at <http://www.php.net>, and the database interface module 110 is a standard structured query language (SQL) database module such as  
30 MySQL, available at <http://www.mysql.com>. The transaction engine 106 allows a user of

the imaging system to perform buy and/or sell operations for financial products and communicates with the stock exchange system 116 to periodically obtain financial data on the financial products. The transaction engine 106 is based on an online broking engine, as used by online broking sites, such as <http://www.etrade.com>. The imaging process is implemented by software modules, being the imaging modules 102 to 112, including text-based and binary program code or instructions stored in non-volatile storage memory of the server. In particular, the visualisation scripts 104 include HTML and PHP scripts that control the imaging process. The scripts 104 are interpreted by the web server 102 and PHP module 108. The imaging process also uses data held in the database 102, that is queried by SQL queries included in or generated from the visualisation scripts 104. However, it will be apparent to those skilled in the art that at least parts of the imaging process executed by the imaging system can be alternatively implemented by dedicated hardware components such as application-specific integrated circuits (ASICs). Another alternative is that software code for executing the imaging process is stored locally on a user's client system 114. The client system may then rely on data stored locally or accessed via the network 118. The client system 114 may be any computer device that would generate an image display, such as a mobile telephone or a personal data assistant (PDA).

The imaging system can be accessed by remote users via the Internet 118. For example, a user of the client system 114, being a standard personal computer system equipped with web browser software such as Microsoft Internet Explorer, can access the imaging system in a standard manner by providing to the web browser a universal resource indicator (URI) assigned to the imaging system. This causes the web browser to send a request to the imaging system, using the hypertext transfer protocol (HTTP). When the web server 102 receives this request, it retrieves one of the visualisation scripts 104, comprising hypertext markup language (HTML) elements, and returns this to the web browser of the client system 114. This causes the web browser to display an imaging page, such as that shown in Figure 4, that allows the user to interact with the imaging system by selecting active controls including the main buttons 402 to 418. For example, the Find Share panel 426

- 10 -

shown in Figure 4 is generated in response to selection of a View Shares button 404 of the main buttons 402 to 418.

The imaging system displays data for a financial product such as a stock by executing the  
 5 imaging process, as shown in Figure 2. The process begins at step 202 by determining  
 which financial product or products are to be displayed. For example, the Find Share  
 panel 426 described above includes a first text box 420 for entering the stock exchange  
 code of a stock, and a second text box 422 for entering a stock name or part thereof. After  
 entering the appropriate information into one of these text boxes 420, 422, a Find  
 10 button 424 is selected to find a stock matching the information provided. When the user  
 selects the Find button 424, the web browser 102 submits the entered information to the  
 web server 102 using an HTTP request that also identifies a stock search script of the  
 visualisation scripts 104, which is used to perform the stock search. The script performs  
 the search by matching the information provided by the user with stock codes or stock  
 15 names stored in the database 112 via an SQL query.

Having identified a stock for display, the financial data to be used to generate the display  
 for that stock is retrieved at step 204 by querying the database 112. The database 112  
 stores all available financial data for each financial product, including buy and sell prices,  
 20 growth, volatility, and other standard variables and measures used to characterise stocks.  
 The database 112 is updated when live financial data is received from remote financial  
 systems (not shown), including live trading data, dividends, and earnings figures. The  
 database 112 stores past, current, and future earnings and dividends forecasts.

25 Any of the stored financial measures can be displayed or used to generate derived values  
 for display, if desired. In the latter case, any derived data measures to be displayed for the  
 stock are generated at step 206. However, once any derived values have been determined,  
 they can be stored in the database 112 if desired. By default, the following four financial  
 measures are used to represent a stock: price, using the measure of the price to earnings  
 30 ratio (P/E), income using the measure of divided yield, growth using the measure of  
 earnings per share growth, and volatility of the stock, using the standard beta value.

- 11 -

However, the user can change any or all of these to visualise any desired combination of financial parameters or measures.

At step 208, the data measures determined at step 206 are normalised to the entire market,  
5 if necessary, using an average value for the entire market stored in the database 112, if  
available. However, as with derived data measures, the resulting normalised data can be  
stored in the database 112 to avoid needless repetition of the normalisation step 206.  
However, if a new data measure is determined at step 206, then the market average will  
need to be determined and this value used to normalise the values for a stock at step 208.

10

At step 210, display data is generated for the stock, based on the normalised data measures.  
The display data is then sent from the web server 102 to the web browser of the client  
system 114 for display to the user. As shown in Figure 5, the result is a View Share  
panel 500 displaying a three-dimensional object 502 representing the selected stock. The  
15 object 502 is a rectangular parallelepiped, and is displayed at the origin of a three  
dimensional co-ordinate system having axes 504 to 508. Although the object 502 is  
preferably solid, as shown, it can alternatively be represented as an open frame structure.  
The dimensions of the object 502 along each of these three axes 504 to 508 represent the  
corresponding values for that stock, normalised to the rest of the market. Thus the  
20 dimension 514 or height of the object 502 along the vertical axis 504 represents the price  
to earnings ratio (P/E) of the stock relative to the overall market. The P/E ratio is derived  
by dividing the current share price by the historic, current or prospective earnings per share  
of the company.

25 The dimension 516 or width of the object 502 along the left-hand horizontal axis 506  
represents the relative income of the stock, using the dividend yield of the stock relative to  
the average of the market. Dividend yield is a measure of the cash return on the  
investment in a stock, and is a better measure of income than the actual dividends alone.  
Dividend yield is determined by dividing the historic, current, or prospective dividend by  
30 the current share price, and is usually expressed as a percentage. A higher dividend yield

shows a high cash return on investment in the form of income to shareholders, while a low dividend yield indicates a low cash return.

5 The dimension 518 or length of the object 502 along the right hand horizontal axis 508 represents the relative growth of the stock, using the measure of earnings per share (EPS) growth of the stock relative to the average of the market. EPS growth is a better measure of growth than earnings growth alone. Earnings per share is calculated by dividing the after tax profit of the company by the number of shares issued. EPS growth is then  
10 calculated by dividing the estimated next year EPS by the current EPS. A high EPS growth shows that analysts are predicting high future profit growth, while a low EPS growth indicates that lower future profit growth is anticipated.

The colour of the object 502 represents the risk of the share relative to the market. Colour is determined from the standard beta value for the stock. By definition, the market has a  
15 beta value of 1, and a beta of 1.2 implies that the stock will move 20% higher or lower when the market rises or falls. Conversely, a beta value of 0.5 implies that the stock's price change will be only half the market's rise or fall. The use of colour allows the user to identify the risk of the share at a glance by simply observing the colour. The level of risk corresponding to the object's colour is indicated by a risk indication bar 510. A red colour  
20 indicates that the share price will move considerably more than the market average change, whilst a blue colour indicates a relatively low risk of share price movements.

To further simplify the interpretation of the displayed data, the dimensions and colour of a displayed object can be quantized or rounded to the nearest of a fixed number of allowed  
25 values. For example, the dimensions of the object 502 shown in Figure 5 can have one of five possible values and the object 502 can have one of five possible colours. Accordingly, the three axes 504 to 508 are displayed with five grid lines to clearly identify the corresponding value, as the edges of the object 502 are aligned with one of these grid lines.

30 Actual un-normalised values for the financial measures corresponding to the three axes 504 to 508 and the object colour for a selected stock can be displayed by moving a

- 13 -

pointing device such as a mouse cursor over the corresponding axis or the object, respectively. For example, as shown in Figure 16, when a mouse icon 1602 is moved over the P/E axis 504, a pop-up window 1604 is displayed, indicating the corresponding P/E ratio of 14.0 for the selected stock. The displayed value can be the exact value for the stock  
5 or rounded to the nearest grid line value, as described above.

Historical data for the displayed financial data measures can be further visualised by selecting an animation tab 512 above the View Share panel 500. This results in the display of a Share Animation panel 612, as shown in Figure 6. The panel 612 includes an  
10 animation control bar 614 that allows the user to control animation of the displayed object 616. A set of radio buttons 618 allows the user to select the time period for the historical share data animation, from periods of three months, six months, one year, three years, or five years. When the user selects a Play button 620 of the animation control bar 614, the displayed object 616 is animated so that its dimensions and colour dynamically change to  
15 represent the changing values of the corresponding financial measures over the period of time selected by the user. A time scale 622 displayed just above the animation control bar 614 allows the user to identify the corresponding points in time during the animation by following the passage of a slider control 624 from the left to the right of the animation control bar 614 as the animation progresses. The slider 624 can alternatively be manually  
20 dragged to any desired location on the animation control bar 614 to view historical stock data at any desired point in time within the selected animation period, or to restrict the animation to a sub-period within that period.

Detailed tabulated data for the stock can be viewed by selecting a detailed tabular view tab  
25 514. This results in a display of a detailed view panel 702, as shown in Figure 7, providing detailed tabular financial information for the share, and a graph 704 of the stock's price over a previous period as selected by the animation period, in this case, twelve months.

Returning to Figure 5, all shares on the market can be viewed by selecting a View All  
30 Shares Tab 518. This results in the display of a View All Shares Panel 802, as shown in Figure 8. The View All Shares panel 802 displays twelve stocks at a time, and provides a

Next button 804 and, on subsequent View All Shares panels, a Previous button (not displayed on the first displayed View All Shares Panel 802) that allow the user to navigate through all of the View All Shares panels to view market stocks in groups of twelve. Alternatively, other methods of navigation can be employed to allow the user to search for  
5 selected pages of stocks, such as using an alphabetical index. As will be apparent from Figure 8, the representation of each stock as a three-dimensional object at the origin of its own spatial co-ordinate system allows financial measures associated with the stocks and relative to the overall market to be easily compared, even by non-expert users. Moreover, the use of colour to represent a stock's volatility allows the user to quickly identify the  
10 volatility of each stock relative to the overall market. As with displays of single stocks, particular financial data values for a stock displayed in the View All Shares Panel 802 can be viewed by moving the mouse icon 1602 over the corresponding axis or object. For example, a beta value of 0.57 for a stock is displayed in a pop-up window 806 when the mouse pointer 1602 is moved over the object 808 corresponding to that stock. The user can  
15 also find stocks similar to a selected stock using a Find Similar Shares button 810, as described below.

The imaging system allows the user to define a stock portfolio, and the user's portfolio can be displayed by selecting a View My Portfolio button 406. When this button 406 is  
20 selected, a View My Portfolio panel 902 is displayed, as shown in Figure 9. The user's portfolio is displayed in groups of twelve shares, and a slider control 904 is provided at the right-hand side of the View My Portfolio panel 902 to allow the user to scroll up and down to display their entire portfolio. This allows the user to easily view and comprehend the current status of their entire portfolio without needing to study detailed tables of numbers  
25 or graphical representations, which can be confusing, particularly for non-expert users.

As described above, the database 112 stores financial data for all stocks. Either continuously, or at periodic intervals, the transaction engine 106 retrieves stock market data from the stock exchange system 116 via the Internet 118. The retrieved data is then  
30 stored in the SQL database 112 by the transaction engine 106 to ensure that the database 112 is always up to date. The visualisation scripts 104 include AUTO-REFRESH

- 15 -

elements so that the View My Portfolio panel 902 is periodically updated to reflect changes in the market. This allows the user to manage their portfolio in real-time.

5 The financial data can be real-time, delayed, historical, or forecast from a variety of sources, including stock markets and exchanges, research and/or analyst and/or broking establishments, other financial institutions, media and other news outlets, owners of the web servers or broadcasters or other third parties.

10 In the preferred embodiment, the display data generated by the visualisation scripts 104 is provided in a standard image format, such as the portable network graphics (PNG) format or as scalable vector graphics (SVG), as described at <http://www.w3.org/TR/SVG>. In an alternative embodiment, the client system 114 includes a module that generates image display data from image description data sent to the client system 114 from the imaging system. For example, the image description data can indicate that a particular object is to be drawn in a particular colour and with particular axis values, and provides the financial values to be displayed in pop-up windows, as described above. The module may be a web browser plug-in module such as a Java applet, as described at <http://java.sun.com/applet>.

20 Individual shares in the user's portfolio can be selected, as indicated by the selected object 906 surrounded by a selection box. A Find Similar Shares button 908 allows the user to identify other stocks with characteristics similar to those of the selected stock. The imaging system selects financial products similar to a selected financial product by executing a financial product selection process, as shown in Figure 3. The process begins at step 302 by determining database query criteria from the selected financial product.

25 This involves identifying the four parameters represented by the selected object 906 for the selected financial product, and constructing a database query for financial products having similar values. The requirement of similarity can be adjusted as required, but by default is satisfied if a value is within 10% of the corresponding value for the selected financial product. At step 304, the database 112 is queried to select any financial products whose

30 parameter measures are similar to those of the selected financial product. At step 306,

display data for the selected financial products is generated from the data retrieved at step 304, and this is then returned for display to the user.

For example, in the case of the stock represented by the selected object 906 indicated by  
 5 the selection box, selection of the Find Similar Shares button 908 results in the display of a  
 Share Search Results panel 1002, as shown in Figure 10. It will be apparent that the eight  
 displayed objects are similar in size, shape and colour to the selected object 906 shown in  
 Figure 9. Thus the financial measures of price to earnings ratio, income, growth, and  
 volatility of the stocks represented by the objects in Figure 10 are all similar to those of the  
 10 stock represented by the selected object 906 shown in Figure 9. The ability to rapidly and  
 easily select stocks similar to a selected stock can be useful in managing a stock portfolio.  
 For example, a stock of the user's portfolio that has been performing particularly well can  
 be used to identify similar stocks in the overall market, and the user may wish to invest in  
 these identified stocks. Conversely, the user can easily identify stocks similar to a stock  
 15 performing particularly poorly.

The user's stock portfolio can alternatively be represented as an aggregate. As shown in  
 Figure 17, selection of a portfolio analyser tab 1702 results in the display of a three-  
 dimensional aggregate object 1704 representing the aggregate of the user's stock portfolio,  
 20 weighted by the price and volume of each stock owned by the user. Thus as the market  
 changes, or when the user trades stocks, the impact of any changes on the user's total  
 portfolio can be readily visualised and evaluated.

As shown in Figure 11, individual stocks can be compared using a Compare Shares  
 25 panel 1102, displayed by selecting a Compare Shares button 410. Information identifying  
 up to four stocks can be entered into text boxes 1104, and a Share Comparison button 1106  
 selected to generate a display of objects representing those stocks. Alternatively, stocks  
 can be compared within a particular sector of the market by selecting one of the Sector  
 Selection buttons 1108. For example, shares within the retail sector can be compared, as  
 30 shown by the Compare Shares by Sector panel 1202 of Figure 12. Thus a user wishing to  
 invest in a particular sector can browse the displayed objects representing stocks within

- 17 -

that sector in order to identify those most attractive for investment purposes. Once a particular stock has been identified, the user can invest in those stocks by selecting a Buy button 416. A stock transaction is then initiated by the transaction engine 106 communicating with the remote stock exchange system 116 to perform the actual stock  
5 buy transaction after the user specifies transaction data such as the number of shares to be purchased and the price per share. Conversely, the user can sell shares from their portfolio by selecting a Sell button 418.

As shown in Figure 5, a View Sector tab 516 can be selected when viewing a selected  
10 stock to display the stock together with other stocks in the same category, sector or industry group.

Stocks matching user-specified criteria can also be found by entering display criteria into a Find by Criteria panel 1302, as shown in Figure 13. The Find by Criteria panel 1302  
15 provides find criteria radio buttons 1304, allowing the user to select relative values for the displayed measures, in this case being price to earnings ratio (P/E), income, growth, and risk, on a relative scale of 1 to 5 for each measure. After the desired values have been selected, a Show my Shares button 1306 is selected to identify stocks whose financial measures match the selected criteria by searching the database 112.

20 The imaging system can also be used to display financial data for mutual funds. The imaging system provides information about the return and risk of individual funds relative to funds in the same sector. As described above in the context of stocks, funds can be compared, and funds with similar characteristics can be identified. Changes with funds  
25 over time can also be displayed as tabular data, in graph form, or as an animated object, as described above. However, in contrast to the default financial measures used to represent shares, the imaging system represents each fund by an object whose dimensions represent the return of the fund over time relative to funds in the same sector, assuming all distributions have been reinvested. As shown in Figure 14, the left hand horizontal axis  
30 1402 indicates fund return over the previous five years; the vertical axis 1404 corresponds to the fund's return over the previous three years, and the right hand horizontal axis 1406

- 18 -

represents the return of the fund over the previous 12 months. The colour of the object 1400 represents the relative risk of the returns of a fund, risk being measured by the volatility of the fund's return relative to the average return of all funds in the same sector. Funds with a relatively high volatility have had more volatile returns over the previous 12 5 months, and funds with a low volatility have had less volatile returns over this period. A View fund/sector tab 1408 displays the selected fund together with other funds in the same fund category or sector.

As shown in Figure 15, a Compare Funds panel 1502 allows the user to easily compare the 10 performance of funds by a simple visual comparison of the objects representing those funds. The differing returns of these funds over the past 1, 3, and 5 years is readily apparent from the different respective dimensions of the displayed objects representing the funds, and the relative risk of each fund is apparent from the colour of its object.

15 Returning to Figure 4, a View My Watchlist button 408 is provided to allow the user to display and monitor the performance of financial products of interest which may or may not be owned by the user. The user can define multiple watchlists of stocks and/or funds.

Although the imaging system has been described in relation to stocks and mutual and other 20 managed funds, it will be apparent that the imaging process and system can be applied to visualise other types of financial data. This includes financial data for financial products such as derivatives, bonds and other financial instruments and/or assets, superannuation and other retirement plans, options and futures, portfolios and other aggregates, real estate, insurance, loans, leases, mortgages and other lending methods and instruments, financial, 25 personal, business and other commercial accounts and balances, credit cards and other financial and/or commercial accounts and transactions.

The ability of the imaging system to generate simple object images representing financial 30 data for a number of financial products in a manner that is easy for non-expert or lay users to comprehend allows such users to compare and evaluate those products. The imaging system constitutes a powerful tool for making decisions in relation to financial products.

- 19 -

In addition to the uses described above, the imaging system can also be used as an evaluation tool on a financial information portal web site such as those at <http://moneycentral.msn.com> and <http://www.morningstar.com>. In such cases, the imaging system is used to undertake research and make judgements about stocks, with the actual stock transactions performed by another tool, site, or party. In this alternative embodiment, the imaging system can access a remote transaction or trading system such as [www.etrade.com](http://www.etrade.com) rather than a stock exchange system to retrieve current financial data and/or to perform financial transactions such as buy and sell operations. The imaging system is also valuable as an educational tool.

Many modifications will be apparent to those skilled in the art without departing from the scope of the present invention as herein described with reference to the accompanying drawings.
